Mechanical alloying is one of the ways how to prepare nanostructured and amorphous metallic materials. In this paper we used this method to prepare Mg-Zn alloy containing 50 wt. % of zinc. Powders produced by milling in a planetary ball mill were consequently compacted by the SPS method, a very fast method which prevents grain coarsening. The prepared samples were subjected to a closer examination - microstructure, phase composition, hardness and short-term thermal stability were studied. We found out that the prepared powder consisted of Mg and Mg-Zn phases, which were very fine and homogeneously distributed. After the SPS compacting, the metastable Mg-Zn phase decomposed and new phases (Mg, MgZn, MgZn$_2$, Mg$_2$Zn$_6$) formed. The compacted sample possessed relatively inhomogeneous microstructure and hardness about 260 HV$_5$. Investigation of the short-term thermal stability was accomplished by annealing at temperatures up to 300 °C. We observed changes in hardness – it regularly decreased up to 200 °C and then it slightly increased.

Keywords: Mg-Zn alloy, mechanical alloying, SPS
